DRAFT GUIDELINES FOR PUBLIC COMMENT

21ST OCTOBER 2020

OPEN FOR COMMENT

UNTIL

5TH NOVEMBER 2020

HIBI – Hypoxic Ischemic Brain Injury
OHCA – Out of Hospital Cardiac Arrest
RCT – Randomised Controlled Trial
ROSC – Return of Spontaneous Circulation
WLST – Withdrawal of Life Sustaining Therapies

1

DRAFT

1888

1889 [h2]Long-term outcome after cardiac arrest

1890 [h3] Long-term outcome

1891 In countries where WLST is uncommon, poor outcome because of HIBI is common.^{376,416} The
1892 prognosis of patients who are still comatose or in an unresponsive wakefulness state one month after
1893 the cardiac arrest is poor and they rarely recover.^{416,417} In contrast, in countries practising WLST, the
1894 majority of survivors are defined as having a ‘good’ neurological outcome based on global outcome
1895 measures such as Cerebral Performance Categories (CPC), modified Rankin Scale (mRS) or the
1896 Glasgow Outcome Scale/Extended (GOS/E).^{279,398,418-420} However, these measures are not sufficiently
1897 sensitive to capture the problems that many of the survivors experience, including cognitive,
1898 emotional and physical problems and fatigue.⁴²¹⁻⁴²³ In fact, approximately 40-50% of the survivors
1899 have long-term cognitive impairments.^{219,424,425} Impairments are mostly mild to moderate and,
1900 although all cognitive domains can be affected, most problems are seen in memory, attention,
1901 processing speed and executive functioning (e.g. planning, organisation, initiation, flexibility).^{219,421,424-}
1902 ⁴²⁶ In general, most cognitive recovery occurs during the first three months after the cardiac arrest.⁴²⁷⁻
1903 ⁴²⁹

1904

DRAFT

1905 Emotional problems are also common. Three to six months after the cardiac arrest anxiety is present
1906 in 15-30% of the survivors and remains in 15-23% at 12 months.⁴³⁰⁻⁴³² Depressive symptoms range
1907 from 13-32% at 3-6 months and decrease to 5-15% at 12 months.⁴³⁰⁻⁴³³ Symptoms of post-traumatic
1908 stress remain in about a quarter of the survivors.^{422,430,433,434} Furthermore, some survivors show
1909 behavioural problems, such as aggressive/uninhibited behaviour or emotional lability.⁴²⁵
1910
1911 Fatigue is also frequently reported and is present in approximately 70% of the survivors at six months
1912 and remains in half of the survivors one year after the event.^{430,435,436} Physical problems, including rib
1913 fractures, muscle weakness and ambulation difficulties, have also been reported.^{423,430,437,438}
1914 However, the impact of survival on physical function has received little attention; when compared
1915 with age and gender-matched populations, reduced physical functioning has been reported in
1916 survivors at 3-months,⁴³⁹ 6-months,⁴³⁸ 12-months⁴²⁰ and three years.⁴³⁷ Almost half of survivors report
1917 limitations because of physical difficulties at 6-months,⁴³⁸ with up to 40% describing mobility
1918 problems^{420,425,430,440} and limitations in usual activities at 12-months.^{420,430,440}
1919
1920 After discharge, most survivors are able to return home and only a small percentage (1–10%) need to
1921 be admitted to a long-term care facility.^{430,440,441} The large majority (82–91%) are independent in their
1922 basic activities of daily living (ADL).^{218,424,437,440} Although most survivors are able to resume their pre-
1923 arrest activities, they experience more restrictions in societal participation compared with myocardial
1924 infarction patients.^{430,436} Cognitive impairments, depression, fatigue and restricted mobility are
1925 negative predictors for future participation.⁴³⁶
1926
1927 Of those who were previously working, 63-85% are able to return to work, although some need to
1928 adapt their working hours or activities.^{420,430,436,437,440,442-444} Decreased likelihood of return to work is
1929 associated with cognitive problems and fatigue, unwitnessed OHCA, absence of bystander CPR,
1930 female gender, higher age and lower socio-economic status.^{436,439,442-444}
1931
1932 General health-related quality of life is, on average, good and overall scores approach normal
1933 population values, as was shown in two systematic reviews and confirmed in several more recent
1934 studies.^{218,420,440,445,446} Cognitive impairments, emotional problems and female gender are associated
1935 with a lower quality of life.^{420,428,438,439,447-452} However, general health related quality of life is, on
1936 average, reported as good with overall scores approaching normal population values, as was shown in
1937 two systematic reviews and confirmed in several more recent studies.^{218,420,440,445,446} However, such
1938 generic assessments lack sufficient granularity to comprehensively capture the breadth of problems

DRAFT

1939 experienced by survivors, with the result that the impact of cardiac arrest survival may be
1940 incompletely captured.²⁷⁹ Supplementing such generic assessment with condition or problem-specific
1941 assessment is recommended.²⁷⁹
1942
1943 More detailed information on recovery and long-term outcome after cardiac arrest, as well as a
1944 description of the current rehabilitation practices in Europe can be found in the epidemiology section
1945 of the European Resuscitation Council Guidelines.⁴⁵³
1946

1947

1948 [h3] In-hospital assessment and follow-up after hospital discharge

1949 [h4] Early rehabilitation and assessment during hospital phase

1950 There are no studies of early rehabilitation interventions for cardiac arrest survivors specifically but
1951 there is substantial overlap with the post-intensive care syndrome (PICS). For other ICU patients,
1952 interventions of early mobilisation and prevention of delirium are described, and similar interventions
1953 are thought to be useful for cardiac arrest patients as well.^{423,454-456} Recommendations in the UK
1954 National Institute for Health and Care Excellence (NICE) guidelines for rehabilitation after critical
1955 illness suggest that individualised rehabilitation plans and information should be provided before
1956 discharge from the ICU and the hospital, based on functional assessments of physical and non-
1957 physical (e.g. cognitive and emotional) impairments.⁴⁵⁷ However, a recent AHA Scientific Statement
1958 focusing on survivorship highlights that discharge planning and organisation of further rehabilitation
1959 needs after cardiac arrest is often lacking.⁴²³

1960 We therefore recommend providing information and performing functional assessments of physical
1961 and non-physical impairments before discharge from the hospital to identify potential rehabilitation
1962 needs and arrange referral for rehabilitation if indicated (Figure X.5).

1963

1964 [h4] Follow-up and screening after hospital discharge

1965 Although cognitive impairments, emotional problems and fatigue are common after cardiac arrest,
1966 these ‘invisible problems’ are not always recognised by healthcare professionals.^{428,436,439,443,452} Since
1967 these problems have a significant impact on long-term outcome and quality of life, follow-up should
1968 be organised in such a way that these problems are detected early enabling appropriate care or
1969 rehabilitation to be arranged.⁴⁵⁸⁻⁴⁶⁰

1970

1971 Evidence on this subject is scarce but results from one RCT showed that an early intervention service
1972 for cardiac arrest survivors and their caregivers improved emotional well-being and quality of life,

DRAFT

1973 resulted in a faster return to work and was cost-effective.^{461,462} This individualised programme is
1974 provided by a specialised nurse, starts soon after discharge from the hospital and comprises one to six
1975 consultations during the first three months. The intervention consists of screening for cognitive and
1976 emotional problems, provision of information and support, and referral to further specialised care if
1977 indicated.^{463,464} There are several other examples of how follow-up after cardiac arrest can be
1978 organised.^{460,465,466} UK NICE guidelines for rehabilitation after critical illness likewise recommend a
1979 follow-up and reassessment for physical and non-physical problems 2-3 months after discharge to
1980 enable identification of remaining problems and to provide further support as needed.⁴⁵⁷ For cardiac
1981 arrest survivors, reassessments have also been suggested at 3, 6 and 12 months.⁴²³

1982

1983 We therefore suggest the systematic follow-up of all cardiac arrest survivors within three months
1984 following hospital discharge which should, at least, include cognitive screening, screening for
1985 emotional problems and fatigue, and the provision of information and support for patients and their
1986 family (Figure X.5).

1987

1988 [h4] Screening for cognitive problems

1989 To screen for cognition, the patient can be asked about common cognitive complaints, such as
1990 memory problems, attention difficulties, distractibility, slowness in thinking, irritability and problems
1991 in initiation, planning, multi-tasking or flexibility. Family members can also provide useful insight into
1992 changes in cognition and behaviour. A structured questionnaire, such as the Informant Questionnaire
1993 of Cognitive decline in the Elderly - Cardiac Arrest version (IQCODE-CA) or the Checklist Cognition and
1994 Emotion (CLCE-24), may be used.^{467,468} Formal cognitive screening is recommended because patients
1995 are not always aware of their cognitive impairments.^{429,458,469} We suggest use of the Montreal
1996 Cognitive Assessment (MoCA), which takes approximately 10 minutes to administer, is easy to use
1997 and freely available in many languages (see www.mocatest.org).^{466,469-471} If there are signs of cognitive
1998 impairment, consider referral to a neuropsychologist for more extensive neuropsychological
1999 assessment or another specialist in cognitive rehabilitation, such as an occupational therapist, should
2000 be considered.⁴⁷²

2001

2002 [h4] Screening for emotional problems and fatigue

2003 To screen for emotional problems, the presence of emotional symptoms, including symptoms of
2004 anxiety, depression and posttraumatic stress, can be explored. Questionnaires, such as the Hospital
2005 Anxiety and Depression Scale (HADS), may be useful.^{423,459,466,473} If severe emotional problems are
2006 detected we suggest referral to a psychologist or psychiatrist for further evaluation and treatment.

DRAFT

2007 We also suggest assessing the presence of fatigue; however, assessment guidance in this population
2008 is currently lacking. In case of severe fatigue consider referral to a specialist in rehabilitation medicine
2009 for advice on appropriate care.

2010

2011 [h4] Provision of information and support for survivor and family members

2012 Exploring the need for and subsequent provision of appropriate information to patients and their
2013 family, preferably both in oral and written form, is recommended.⁴⁷⁴ The active engagement of
2014 survivors and their family members to better understand their needs and how they would like to
2015 receive such information, is recommended as part of this process.⁴²³ Information should cover not
2016 only medical subjects such as cardiac disease, risk factors, medication and ICD, but can also address
2017 other topics such as potential physical, cognitive and emotional changes and fatigue, resuming daily
2018 activities, driving and work, relationship and sexuality.^{463,474-477}
2019 It is also important to monitor the well-being of family members because the impact and burden can
2020 be substantial.^{476,478} Partners often have emotional problems, including symptoms of anxiety and
2021 posttraumatic stress, especially in women and those who witnessed the resuscitation.^{479,480} Consider
2022 referral to a social worker, psychologist or psychiatrist when indicated.

2023

2024

2025 [h2] Rehabilitation after cardiac arrest

2026 [h3] Neurological rehabilitation

2027 In the presence of severe HIBI, patients may require inpatient neurological rehabilitation and,
2028 although the evidence is limited, several small retrospective studies have shown that functional
2029 improvements can be achieved, reducing the burden of care on the family and society.⁴⁸¹⁻⁴⁸³

2030

2031 Although specific guidelines and evidence for neurological rehabilitation after cardiac arrest is lacking,
2032 there is more evidence and multiple clinical practice guidelines for other types of acquired brain
2033 injury such as traumatic brain injury and stroke which can guide the treatment of patients with HIBI
2034 due to cardiac arrest.⁴⁸⁴⁻⁴⁸⁶ These guidelines provide practical recommendations on topics such as
2035 motor function, physical rehabilitation, cognition, communication, activities of daily living and
2036 psychosocial issues. Guidelines on rehabilitation after critical illness/ post-intensive care syndrome
2037 (PICS) can also be useful.^{457,487-489}

2038

2039 [h3] Cardiac rehabilitation

DRAFT

2040 Many cardiac arrest survivors are eligible to enrol in a cardiac rehabilitation programme.⁴⁹⁰ There is
2041 evidence that cardiac rehabilitation reduces cardiovascular mortality and hospital admissions,
2042 improves quality of life, and is cost-effective.⁴⁹⁰⁻⁴⁹³ Cardiac rehabilitation programmes are mostly
2043 generic programmes, in which patients with different cardiac diseases, e.g. post-acute coronary
2044 syndrome, heart failure or post cardiac surgery, can participate. It involves exercise training, risk
2045 factor management, lifestyle advice, education and psychological support.⁴⁹¹ Cardiac rehabilitation is
2046 frequently offered as a centre-based out-patient service, but can also be organised in a home-based
2047 setting in combination with telemonitoring.⁴⁹⁴ In specific cases it can be provided as an inpatient
2048 programme.⁴⁹¹ Not all cardiac arrest survivors are eligible for or have access to cardiac rehabilitation,
2049 either because of the cause of the cardiac arrest or because of variation in national or insurance
2050 policies.⁴⁹⁵

2051

2052 Within cardiac rehabilitation programmes little attention is paid to potential cognitive problems.
2053 Among cardiac patients in general, cognitive and emotional problems have not been addressed well
2054 in cardiac rehabilitation programmes.⁴⁹⁶⁻⁴⁹⁸ For cardiac arrest survivors, there are some examples in
2055 which cardiac and cognitive rehabilitation have been integrated, although evidence of effects is still
2056 lacking.^{460,466}

2057

2058 [h3] Cognitive rehabilitation, fatigue management and psychosocial interventions

2059 The goal of cognitive rehabilitation is to reduce the impact of cognitive impairments and to improve
2060 overall well-being and daily functioning.⁴⁹⁹ It can include additional neuropsychological assessment to
2061 get more insight into the nature and severity of the cognitive impairments and other influencing
2062 factors. Extensive patient education is essential to give the patient and their family more insight into
2063 what has changed in their cognition and behaviour. Compensation strategies, such as memory
2064 strategy training and metacognitive strategy training (e.g. self-monitoring, self-regulation and
2065 planning ahead) and the use of external (memory) aids may be helpful.⁴⁷² Although there are no
2066 specific studies on the effects of cognitive rehabilitation in patients with brain injury caused by cardiac
2067 arrest, a recent evidence-based review on cognitive rehabilitation after stroke and traumatic brain
2068 injury, can serve as a guideline.⁴⁷²

2069

2070 Fatigue management can be included in cognitive rehabilitation or provided alone.⁵⁰⁰ [Wylie 2018
2071 CNC50] There is weak evidence that a 4-week telephone intervention, based on energy conservation
2072 and problem-solving therapy, can be of benefit for cardiac arrest survivors with moderate to severe
2073 fatigue.^{501,502}

DRAFT

2074

2075 There is also evidence that psychosocial interventions specifically designed for cardiac arrest survivors

2076 can be valuable. Two RCTs showed benefit from nurse-led psychosocial interventions, either by

2077 telephone or face-to-face.^{503,504} These interventions addressed self-management, coping strategies,

2078 relaxation, information and health education.^{504,505}

2079

2080 There are currently no studies on the effectiveness of social support networks or virtual/online

2081 forums, but these may have additional value as a new and easily accessible form of psychosocial

2082 support and information after cardiac arrest.⁴²³

2083
